Although most of the computing power is in the CAD machine (or workstation), most users work from the perspective of the designer (or drafter) in the 3D model. As a result, the two ends of a design are built separately. A designer (or drafter) first creates 2D drawings on a computer, and then sends those drawings to the production team for "trimming" and assembly. Many potential problems are discovered at this stage of the process, such as not having the proper room in the assembly line. The computer CAD drawing of the sculptured piece is used as a tool to produce the final metal sculpt. This is a key factor in the success of this particular project. If you do not have the CAD file, your sculpting process will have limitations. It would be like trying to sculpt your piece with nothing but a paper-and-pencil model. The CAD file is an electronic "blueprint" of your piece. It includes the entire project, and also makes it easier to coordinate the work of all your sub-contractors. Although this sculpture is the result of a 3D scan, it was developed to look like a hand carved piece. So, it is very important to use a hand carved texture to give it the correct wood finish. Otherwise, it will look too smooth and plastic-like. AutoCAD is a great tool to use if you are doing any kind of CAD or drafting, whether you are an architect, engineer, architectural designer, woodworker, production designer, 3D scanner, and so on. Step 1 Using the Rotate tool (V), click on the Rotate button on the toolbar and then click on the object that you want to rotate, holding down the left mouse button. The Rotate tool dialog box opens. Using the rotation arrows, you can move the rotation of the object. If you want to make sure the rotation is accurate, use the "Snap to Grid" button. Step 2 Select the Line tool (V). Click on the object and use the cursor keys to move the line around the object. The Line tool can be used to create a straight or curved line around the object. When you make a line, you can change its color, thickness, and line

Single-unit recordings from the cerebellar cortex of the rat were used to study the neural correlates of learning and forgetting. Purkinje cells (PCs) in all lobules of the anterior lobe of the cerebellar cortex showed strong heterogeneous response-modification following classical conditioning of a simple eye-blink response to auditory stimuli. During conditioning, PCs showed significant response modifications in the duration, amplitude and phase of the slow waves and the number of spikes within the slow-wave complexes. As the conditioned response increased in magnitude over the next 30 min, changes in the average spike rate and the duration and amplitude of the slow waves persisted or increased, whereas the number of spikes in the slow-wave complexes progressively decreased. Thus the excitability of PCs changed as a function of the strength of the conditioning stimulus. This same sequence of events occurred when the response was extinguished following the learning of the conditioned response. PCs in the anterior lobe, ventral cortex and intermediate lobe of the cerebellum also responded to the presentation of conditioned stimuli at different time intervals after the conditioning stimulus. The latency for conditioned responses changed as a function of the number of conditioning trials for responses to the same conditioned stimulus. Purkinje cells in the ventral cortex and the intermediate lobe did not change their average spike rate or the duration or phase of their slow waves following conditioning, while in the anterior lobe, PCs showed significant response-modification. Purkinje cells in the ventral cortex showed a monotonic increase in the magnitude of conditioned responses as a function of conditioning trials.
